**Abstract** The Bhopal gas tragedy in 1984 was the major turning point in India; this made organizations to adopt various safety policies and procedures. Organizations also found out that implementation of healthy working conditions create a positive impact on the society and also encourages employees to work efficiently. A questionnaire-based survey was considered as it is one of the most frequently used and widely accepted methods for measuring safety climate. A questionnaire was developed consisting of 20 safety climate components with 81 questions and was administered to four chemical industrial sectors in Karnataka, India. This was distributed among 370 employees, and only 340 responses were found to be valid. Exploratory Factor Analysis was carried out on the surveyed data to reduce the number of components. The Principal Axis Factor was used to extract the predominant components; three predominant components were identified and the Partial Least Squares regression was used to determine the relationship that these three components shared with safety climate.

**Keywords** Safety climate, Chemical industries, India

---

## 1. Introduction

In many densely populated countries, safety in the chemical industry is an important issue. Bhopal gas tragedy (1984) in India and many other accidents in chemical industries across the world made organizations adopt various safety policies and procedures. But even since then many accidents are recorded in various chemical industries across India.

A Study by Kennedy and Kirwan [1] suggested that measuring safety climate is a better option to quantify the safety of an organization as it surpasses many of the obstacles of traditional safety measures. Safety climate can be defined as the molar perception of employees towards their organization on safety. A significant relationship between a positive safety climate and fewer accidents has been demonstrated in hazardous industries, such as chemical and nuclear processing ([2], [3]). The factors that affect safety climate across various industries differ because of differences in geography, demography, and style of management.

Vinod Kumar and Bhasi [4] conducted an in-depth study on safety climate in accidents from hazardous chemical industries in Kerala, India. The study identified eight safety climate factors and provided benchmark scores for each

factor. Further, these scores were used to evaluate the safety of an organization.

India is a diverse country where people differ significantly in culture, literacy rate, attitude and work style. Safety still remains a concern in many industries across the country. So far only one research has been carried out in the chemical industry sector of India. So it is necessary to conduct a study in chemical industries in Karnataka to determine the relation of various safety components and safety climate.

## 2. Literature Review

Ian Donald and David Canter [5] conducted a survey in ten chemical sites in UK with question set consisting of ten scales. The aim was to establish the reliability of a safety attitude assessment scales and safety climate in the chemical industry. The results indicated that there is a strong and clear association between safety attitude and accident performance of a company.

Vinod Kumar and Bhasi [4] conducted a thorough survey using a questionnaire which was conducted for accidents among 2536 employees in eight major hazardous chemical sectors in Kerala. The safety climate scores were significantly negatively correlated with self-reported accident rates. The study identified eight safety climate factors and provided benchmark scores for each factor, which can then be used to evaluate the status of safety in an organization at a given point of time.

This literature review illustrates the extent to which safety climate has been studied in the chemical sector. Only a few studies exist in the chemical sector pertaining to safety

climate; so far only one research has been carried out in India. So this is the reason for conducting the study for the in chemical sector of Karnataka.

### 3. Methodology

#### 3.1. Questionnaire Design

A questionnaire- based survey was considered as it is one of the frequently used and widely accepted methods for measuring safety climate in an organization.

After conducting a literature review, the frequency of the components used in the previous studies were identified and a draft questionnaire was designed containing 20 safety climate components consisting of 81 questions averaging about 4 questions for each safety climate component. A pilot study was conducted in order to obtain the feedback about the reliability of items. The questions were distributed in English and the local language of Kannada.

#### 3.2. Estimation of Sample Size

A convenient sampling approach was adopted for this study. A total of 370 questionnaires were distributed to 4 chemical industries in the State of Karnataka; however, only 340 responses were found to be valid.

**Table 1.** Demographics of study sample

Demographic Variable	Level	Number of Respondents	Percentage
Gender	Males	327	96.17
	Females	13	3.83
Age	18 to 25 years	31	9.11
	26 to 40 years	158	46.47
	Above 40 years	151	44.41
Experience	1 to 5 years	65	19.11
	6 to 15 years	141	41.47
	More than 15 years	134	39.41
Education	Post Graduate	59	17.35
	Graduate	108	31.76
	Undergraduate	22	6.47
	Diploma	34	10
	ITI	69	20.29
	Others	48	14.11
Nature of job	Technical	213	62.64
	Non - Technical	127	37.35
Designation	Worker	239	70.29
	Supervisor / Manager	93	27.35
	CEO	8	2.35
Department	Production	180	52.94
	Maintenance	72	21.76
	Safety	15	4.41
	Others	73	21.47

From Table 1, it can be seen that more than 95% of the respondents were males and the rest were females. Around 47% of the respondents were in the age range of 26-40 years. Over 41% of the respondents had an experience of 6-15 years and also over 30% of the respondents were graduates. Around 70% of the respondents were workers and the rest of them were supervisors and CEO. Over 52% of the respondents belonged to the production department.

#### 3.3. Data Analysis

The collected data was subjected to statistical analyses using R v3.4.3. In order to reduce the dimensionality of the safety climate components, the Exploratory Factor Analysis was used. The Principal Axis Factor was used to extract the predominant components and the Chi-Square test was conducted to determine the associations between safety climate and the demographic variables. The Partial Least Squares (PLS) regression was used to determine the relationship that the safety components shared with safety climate.

## 4. Results

#### 4.1. Components

The Parallel Analysis was used to determine the number of components that best explained the variation in the data. The Parallel Analysis compares the variation explained by the number of factors with randomly- generated data and checks if the differences in the variances observed are statistically significant. Such a procedure combines the power of statistical hypothesis testing and the domain knowledge that comes with experience to determine the factors.

A Parallel Analysis of the collected data showed that a combination of three factors best explained the variation in the data. The details of these three factors are provided in Tables 3 and 4.

Only items with standardized loadings greater than or equal to absolute 0.5 were considered. The names of the components were finalized based on the items present in the components.

## 5. Safety Climate Measurement Model

#### 5.1. Model Validity

Three measurement properties need to be examined to ensure satisfactory validity and reliability of the model ([6], [7]).

First there is the individual item reliability indicated by the correlations or loadings, with 0.7 as cutoff value. Second there is the convergent validity, evaluated by Cronbach's Alpha. The cut-off value generally accepted as the threshold is 0.7 [8]. The results obtained in Table 3 show that the obtained Cronbach's alpha well exceeds either the cutoff,

which indicates good convergent validity. The third measurement property is discriminant validity, indicated by the average variance explained. This measure for the current model is indicated in Table 3. This should be greater than the squared intercorrelations between the elements, which are indicated in Table 4.

Thus it can be concluded that the Safety Administration, Safety Behavior and Deviant Behavior measure the final safety path model shown in Fig 2 with a good precision.

**Table 2.** Factors and Corresponding Items

Item	Safety Administration	Safety Behavior	Deviant Behavior
Management encourages the leadership and provides necessary requirements	0.742		
My company provides innovative techniques in promoting safety	0.695		
My company believe in teamwork and takes action to promote teamwork	0.67		
My company provide sufficient safety equipment for the workers	0.665		
We have a effective safety leadership in my company	0.659		
Many workers in the factory are provided First aid training, fire fighting and their names have been displayed in the factory	0.619		
I know the hazardous chemicals used and their quantities stored in the factory	0.61		
Risk assessment study has been carried out in the factory	0.604		
Newly recruits are adequately trained, orientation is provided to learn about various safety rules and procedures	0.602		
Management provided accidental insurance policy, public liability insurance in the factory	0.594		
Safety inspections, audits are carried out regularly	0.593		
My company provides ISI marked safety equipment to the workers	0.592		
To assess hazards in my work area adequate safety training is given to me	0.579		
I use all necessary PPE's to do my job	0.571		
Safety checks, pep talks and safety meetings are useful to prevent accidents and dangerous occurrences	0.571		
My company gives a very comprehensive training to the employees on health and safety issues	0.562		
My management takes care about the occupational hazards and their remedies	0.535		
I am trained adequately to respond to emergency situations that take place in my workplace	0.532		
In my company PPE's are selected and monitored by the safety dept	0.531		
I know the hazards associated in the process and the risk involved in the workplace	0.523		
Contract workers are provided sufficient safety training and orientation of potential hazards	0.506		
I know how to reduce the risk of accidents and incidents in the workplace		0.743	
I feel that it is important to promote safety programmes		0.709	
I feel that it is very necessary to maintain safety in my workplace at all times		0.675	
I know the different types of hazards which are associated with my job		0.651	
I know how to perform my job in a safe manner		0.634	
While carrying out my job I follow correct safety procedures and rules		0.617	
I am clear about what my responsibilities are for health and safety		0.571	
I feel that it is necessary to put efforts to the incidents at workplace		0.549	
I feel that management takes corrective actions only when they are told about the unsafe practices		0.549	
In order to improve the safety at my workplace I put extra effort		0.531	
Sometime due to fatigue and stress, I deviate safety procedures of work			0.6
Sometimes due to heavy work I do not wear PPE's			0.564
Average Variance Explained	0.159	0.094	0.034

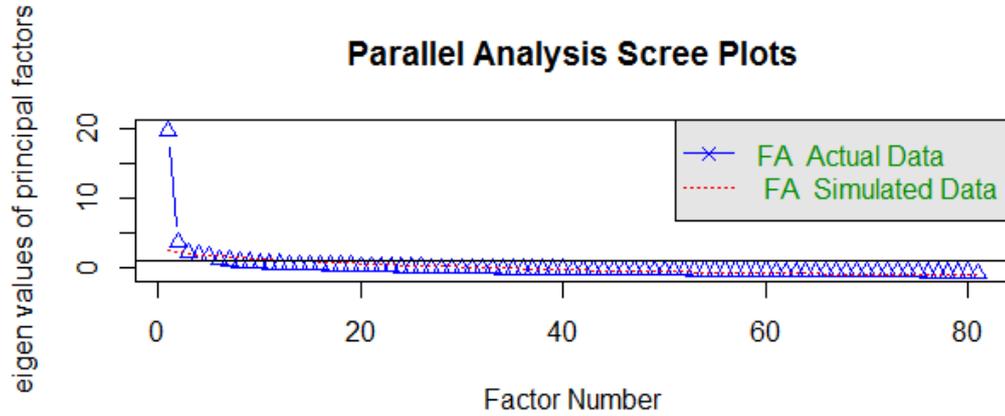

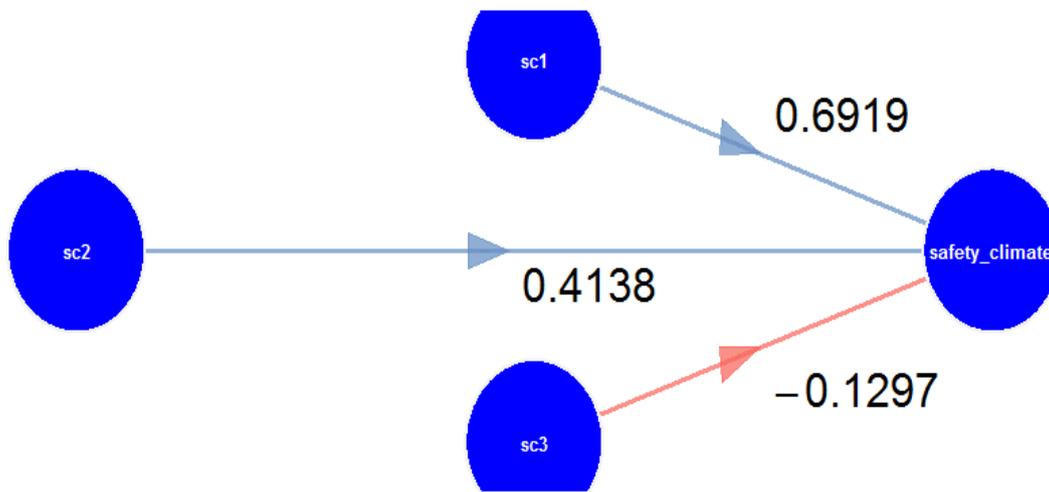

Figure 1. Parallel Analysis plot of factors. Notes. FA = Factor Analysis

Table 3. Distribution of items amongst the components

Group of Questions	Number of Items	Cronbach Alpha	Dillon-Goldstein Rho	Average Variance Extracted
Safety Administration	21	0.924	0.932	0.397
Safety Behavior	10	0.874	0.899	0.472
Deviant Behavior	2	0.786	0.903	0.823

Table 4. Inter-correlations among the four safety climate components

Principal Factors	Safety Administration	Safety Behavior	Deviant Behavior	Safety Climate
Safety Administration	1			
Safety Behavior	0.416	1		
Deviant Behavior	-0.216	-0.283	1	
Safety Climate	0.911	0.769	-0.396	1

Description: SC1= Safety Administration, SC2= Safety Behavior, SC3= Deviant Behavior

Figure 2. Parallel Analysis plot

### 5.2. Model Assessment

The descriptive or predictive power of any PLS model can be determined by examining the  $R^2$  value of the dependent constructs.  $R^2$  indicates the amount of variance in the endogenous latent variable explained by its independent latent variables [9]. The  $R^2$  value of 0.99, obtained for this particular model, implies that around 99% of the variation in safety climate is explained by the components.

Path models indicate the effect of a variable on the safety climate. The greater the magnitude of the path coefficient, the stronger the effect on the safety climate. Fig 2 shows that the safety component 1 has a stronger effect on the safety climate, whereas the safety component 2 has a moderate effect on the safety climate. The safety component 3 has a weak and negative relationship with the safety climate.

## 6. Discussion

This paper explored the subject of safety climate in the chemical industry of India. The questionnaire was distributed to 370 respondents out of which 340 responses were usable. Then the collected data was subjected to factor analysis to determine the significant components. These components were then used to study the relationship with safety climate.

The statistical analysis yielded three components of safety climate:

- Safety Administration (SC1)
- Safety Behavior (SC2)
- Deviant Behaviors (SC3)

### 6.1. Safety Administration

The Safety Administration can be defined as all activities of planning, implementation and execution for safety that include the formation of safety rules and procedures, risk assessment and justification, emergency preparedness, safety training and development, deciding on PPE, budgeting for safety, inculcation of teamwork for safety and promoting the spirit of innovation towards safety.

So far many studies have been carried out on the safety climate in various sectors but none of these studies has considered or identified Safety Administration as an important component of safety climate. But from the above study conducted, it can be noted that Safety Administration had a positive correlation with safety climate; the strength of this component was also higher compared to the other components.

### 6.2. Safety Behavior

Cooper and Phillips [10] stated that the safety climate of a facility varied over time with the completion of remedial actions of improvements in the safety behavior.

### 6.3. Deviant Behavior

Vinodkumar and Bhasi [4], Donald and Canter [5] have conducted studies for chemical industries, out of which no study has identified Deviant Behavior as one of the components which affects safety climate. Researchers have carried out studies in safety climate across various sectors but none of the studies have identified the relation between Deviant Behavior and safety climate as a significant one.

From the above study, it can be concluded that Deviant Behavior has a negative correlation with safety climate.

## 7. Conclusions

The Safety climate for the chemical industry of Karnataka is associated with Safety Administration, Safety Behavior and Deviant Behaviors. Safety Administration and Safety

Behavior showed a positive relationship with the safety climate whereas the Deviant Behavior had a negative impact on safety climate. The objective of the paper is to explicate safety climate in the chemical industry scenario by building a model that quantifies the relationship which safety climate has with its components.

## ACKNOWLEDGEMENTS

This paper was completed with the constant support and guidance provided by Rashmi, Pranesh and Anusha, Department of Industrial Engineering & Management, JSS Academy of Technical Education. The data which was used in the study was provided by T.V. Narayanappa, Deputy Director of Factories, Department of Factories, Boilers, Industrial Safety and Health, Government of Karnataka, India.
